An aerial photograph taken from the perspective of someone on an aircraft, looking out over a vast, dense green forest. The dark, metallic wing of the plane is visible in the lower foreground, extending towards the right. In the distance, a tall, thin tower stands against the blue sky. The sky is filled with scattered white clouds. The overall scene is bright and clear, suggesting a sunny day.

**Seeing the tree for the forest:  
New ways to use  
eddy covariance to  
map landscape fluxes**

# Take home messages

- I do not work in urban systems, but have operated very tall tower eddy covariance and atmospheric observations for a long-time
  - I'm also involved in providing science advice to ICOS and am invested in seeing it succeed in this area
- Co-location of boundary-layer, atmospheric mole fraction, and ecosystem flux measurements affords opportunities for robust estimation of greenhouse gas sources and sinks
- Landscape heterogeneity is a challenge for traditional eddy covariance but not impossible to solve
- Tall tower eddy covariance does require additional considerations for quality control

# Representativeness of Eddy-Covariance flux footprints for areas surrounding AmeriFlux sites

Chu et al., AgForMet, 2021

# How do we deal with this?

- Ignore it
- Build a lot of towers
  - Combine with tall tower boundary-layer observations
- Do something different with flux towers
  - Spatial and temporal resolved fluxes
  - Environmental Response Functions
- Some challenges with very tall towers
  - Storage flux, energy balance, footprints
- Final thoughts

Ignore it!
